

Redeploying Water Retention: Green Infrastructure and Phosphorus Capture in the LWB

Joey Simoes, MSc, EIT, Contact: joeysimoes@gmail.com

Lake Winnipeg Basin Program Symposium

March 21st, 2019

Background

Water Retention in Manitoba

When poorly managed or abandoned

- Overgrown with invasive plant species
- Reduced flood storage (often their main purpose)
- Can result in additional phosphorus loading

What can we do?

- Study the redeployment of water retention sites as green infrastructure with greater priority on P-removal

Selection of study site

- Seine-Rat River watershed identified as source of high P-load to the Lake Winnipeg Basin
- De Salaberry Water retention is the largest of its kind under the conservation district's management

Background

De Salaberry Water Retention

Features

- Capacity of 376 acre/ft at dyke
- Outflow through 600 mm culvert
- 25 m emergency spillway
- Designed to drain from full in about 16 days

History

- Constructed between 2010-2012
- First use in spring 2013
- Spillway reconstructed for the 2017 spring runoff

Objectives

Develop a Nature Based Solution for P-reduction in the LWB

- 1) Create a hydrologic and nutrient transport model at De Salaberry
 - Monitor site parameters
- 2) Implement beneficial management practices
 - Water level control and selective harvesting
- 3) Create inventory of suitable water retention sites in the LWB
 - Extrapolate benefits from implementation of management strategy

Objectives

Evaluation of environmental and economic co-benefits

Flood storage performance

- Derived from hydrometric monitoring

Mass of P captured

- Water quality in vs out of site

Area of wetland habitat restored

- Monitoring of wetland health and biodiversity

CO₂ displaced and economic incentives

- Sale and use of biomass as fuel, livestock bedding, and compost

Cost efficiency

- Improved management vs new projects

Current Progress

Hydrodynamics and Monitoring

- Water level
- Water quality
- Flow

- Known flow path
- Culvert/Spillway
- Flow barrier

Immediate Roadmap: 2019

March

- Compile existing data and characterize watershed
- Initiate field monitoring program

April

- Collect data during spring runoff
- Begin hydrologic and nutrient model development
 - We're open to suggestions!

May to June

- Begin model calibration using 2019 field data
- Develop management plan

July

- Reporting of 1st year results

Roadmap: 2019-2021

Remainder of 2019 to 2021

- Continue monitoring and modeling efforts to evolve management plan
- Extrapolate results to applicable water retention projects in the LWB to better quantify larger scale benefits
 - Flood storage performance
 - Mass of P captured
 - Area of wetland habitat restored
 - CO₂ displaced and economic incentives
 - Cost efficiency
